Microprocessor Supervisory Circuit

GENERAL DESCRIPTION

The SGM706B microprocessor supervisory circuit reduces the complexity and number of components required to monitor power supply and monitor microprocessor activity. It significantly improves system reliability and accuracy compared to separate ICs or discrete components.

The SGM706B provides power supply monitoring circuitry that generates a reset output during power-up, power-down and brownout conditions. The reset output remains operational with $V_{\rm CC}$ as low as 1V. Independent watchdog monitoring circuitry is also provided. This is activated if the watchdog input has not been toggled within 1.6 seconds.

In addition, there is a 1.25V threshold detector for power-fail warning, low-battery detection, or monitoring an additional power supply. An active-low manual reset input (nMR) is also included.

The SGM706B is available in Green SOIC-8 and MSOP-8 packages. It operates over an ambient temperature range of -40°C to +125°C.

FEATURES

- Ultra-Low Supply Current: < 1μA (TYP)
- Precision Supply-Voltage Monitor
 - 4.63V for SGM706B-L
 - 4.38V for SGM706B-M
 - 4.0V for SGM706B-J
 - 3.08V for SGM706B-T
 - 2.93V for SGM706B-S
 - 2.63V for SGM706B-R
- Guaranteed nRESET Valid at V_{cc} = 1V
- 200ms Reset Pulse Width
- Debounced TTL/CMOS-Compatible
- Manual Reset Input
- Independent Watchdog Timer (1.6s) Timeout
- Voltage Monitor for Power-Fail or Low-Battery Warning
- -40°C to +125°C Operating Temperature Range
- Available in Green SOIC-8 and MSOP-8 Packages

OVERSTRESS CAUTION

Stresses beyond those listed in Absolute Maximum Ratings may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability. Functional operation of the device at any conditions beyond those indicated in the Recommended Operating Conditions section is not implied.

ESD SENSITIVITY CAUTION

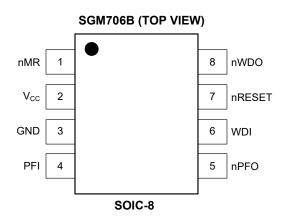

This integrated circuit can be damaged by ESD if you don't pay attention to ESD protection. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

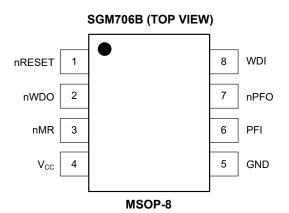

DISCLAIMER

SG Micro Corp reserves the right to make any change in circuit design, or specifications without prior notice.

PIN CONFIGURATIONS

PIN DESCRIPTION

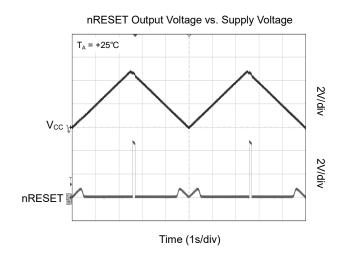

PIN		NAME	FUNCTION
SOIC-8	MSOP-8	NAME	FUNCTION
1	3	nMR	Manual Reset Input Pin. Manual reset input triggers a reset pulse when pulled below 0.8V. This active-low input has an internal 234 μ A (V _{CC} = +5V) pull-up current. It can be driven from a TTL or CMOS logic line as well as shorted to ground with a switch.
2	4	V _{CC}	Power Supply Voltage. Power supply voltage that is monitored.
3	5	GND	Ground. 0V ground reference for all signals.
4	6	PFI	Power-Fail Voltage Monitor Input Pin. When PFI is less than 1.25V, nPFO goes low. Connect PFI to GND or V _{CC} when not used.
5	7	nPFO	Power-Fail Output Pin. Power-fail output goes low and sinks current when PFI is less than 1.25V; otherwise nPFO stays high.
6	8	WDI	Watchdog Input Pin. If WDI remains high or low for 1.6s, the internal watchdog timer runs out and nWDO goes low. Floating WDI or connecting WDI to a high-impedance three-state buffer disables the watchdog feature. The internal watchdog timer clears whenever reset is asserted, WDI is three-stated, or WDI sees a rising or falling edge.
7	1	nRESET	Reset Pin. Active-low reset output pulses low for 200ms when triggered, and stays low whenever V_{CC} is below the reset threshold (4.63V for SGM706B-L, 4.38V for SGM706B-M, 4.0V for SGM706B-J, 3.08V for SGM706B-T and 2.93V for SGM706B-S, 2.63V for SGM706B-R). It remains low for 200ms after V_{CC} rises above the reset threshold or nMR goes from low to high. A watchdog timeout will not trigger nRESET unless nWDO is connected to nMR.
8	2	nWDO	Watchdog Output Pin. Watchdog output pulls low when the internal watchdog timer finishes its 1.6sec count and does not go high again until the watchdog is cleared. nWDO also goes low during low-line conditions. Whenever V_{CC} is below the reset threshold, nWDO stays low; however, unlike nRESET, nWDO does not have a minimum pulse width. As soon as V_{CC} rises above the reset threshold, nWDO goes high with no delay.

TYPICAL PERFORMANCE CHARACTERISTICS (continued)

FUNCTIONAL BLOCK DIAGRAM

APPLICATION NOTES

Ensuring a Valid nRESET Output Down to $V_{CC} = 0V$

When V_{CC} falls below 1V, the SGM706B nRESET output no longer sinks current, it becomes an open circuit. High-impedance CMOS logic inputs can drift to undetermined voltages if left undriven. If a pull-down resistor is added to the nRESET pin as shown in Figure 1, any stray charge or leakage currents will be drained to ground, holding nRESET low. Resistor value (R1) is not critical. It should be about $100k\Omega$, large enough not to load nRESET and small enough to pull nRESET to ground.

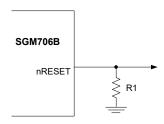

Figure 1. nRESET Valid to Ground Circuit

Monitoring Voltages Other Than the Unregulated DC Input

Monitor voltages other than the unregulated DC by connecting a voltage divider to PFI and adjusting the ratio appropriately. If required, add hysteresis by connecting a resistor (with a value approximately 10 times the sum of the two resistors in the potential divider network) between PFI and nPFO. A capacitor between PFI and GND will reduce the power-fail circuit's sensitivity to high-frequency noise on the line being monitored. nRESET can be asserted on other voltages in addition to the +5V V $_{\rm CC}$ line. Connect nPFO to nMR to initiate a nRESET pulse when PFI drops below 1.25V. Figure 2 shows the SGM706B configured to assert nRESET when the +5V supply falls below the reset threshold, or when the +12V supply falls below approximately 11V.

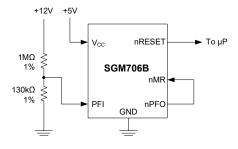

Figure 2. Monitoring Both +5V and +12V

Monitoring a Negative Voltage

The power-fail comparator can also monitor a negative supply rail (Figure 3). When the negative rail is good (a negative voltage of large magnitude), nPFO is low, and when the negative rail is degraded (a negative voltage of lesser magnitude), nPFO is high. By adding the resistors and transistor as shown, a high nPFO triggers reset. As long as nPFO remains high, the SGM706B will keep reset asserted (nRESET = low). Note that this circuit's accuracy depends on the PFI threshold tolerance, the V_{CC} line, and the resistors.

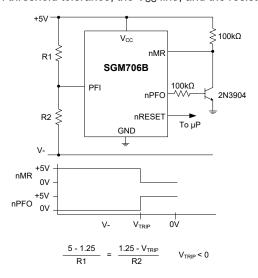

Figure 3. Monitoring a Negative Voltage

Interfacing to µPs with Bidirectional Reset Pins

 μ Ps with bidirectional reset pins, such as the Motorola 68HC11 series, can contend with the SGM706B nRESET output. If, for example, the nRESET output is driven high and the microprocessor wants to pull it low, indeterminate logic levels may result in. To correct this, connect a 4.7k Ω resistor between the nRESET output and the μ P reset I/O, as show in Figure 4. Buffer the nRESET output to other system components.

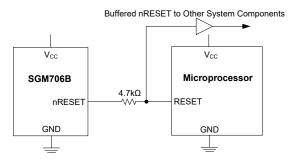

Figure 4. Interfacing to Microprocessors with Bidirectional Reset I/O

Low-Cost, Microprocessor Supervisory Circuit
